CS598: Deep Learning with Graphs, 2024 Fall

<https://ulab-uiuc.github.io/CS598/>

Recap: “Shallow” Encoding

- Simplest encoding approach: **encoder is just an embedding-lookup**

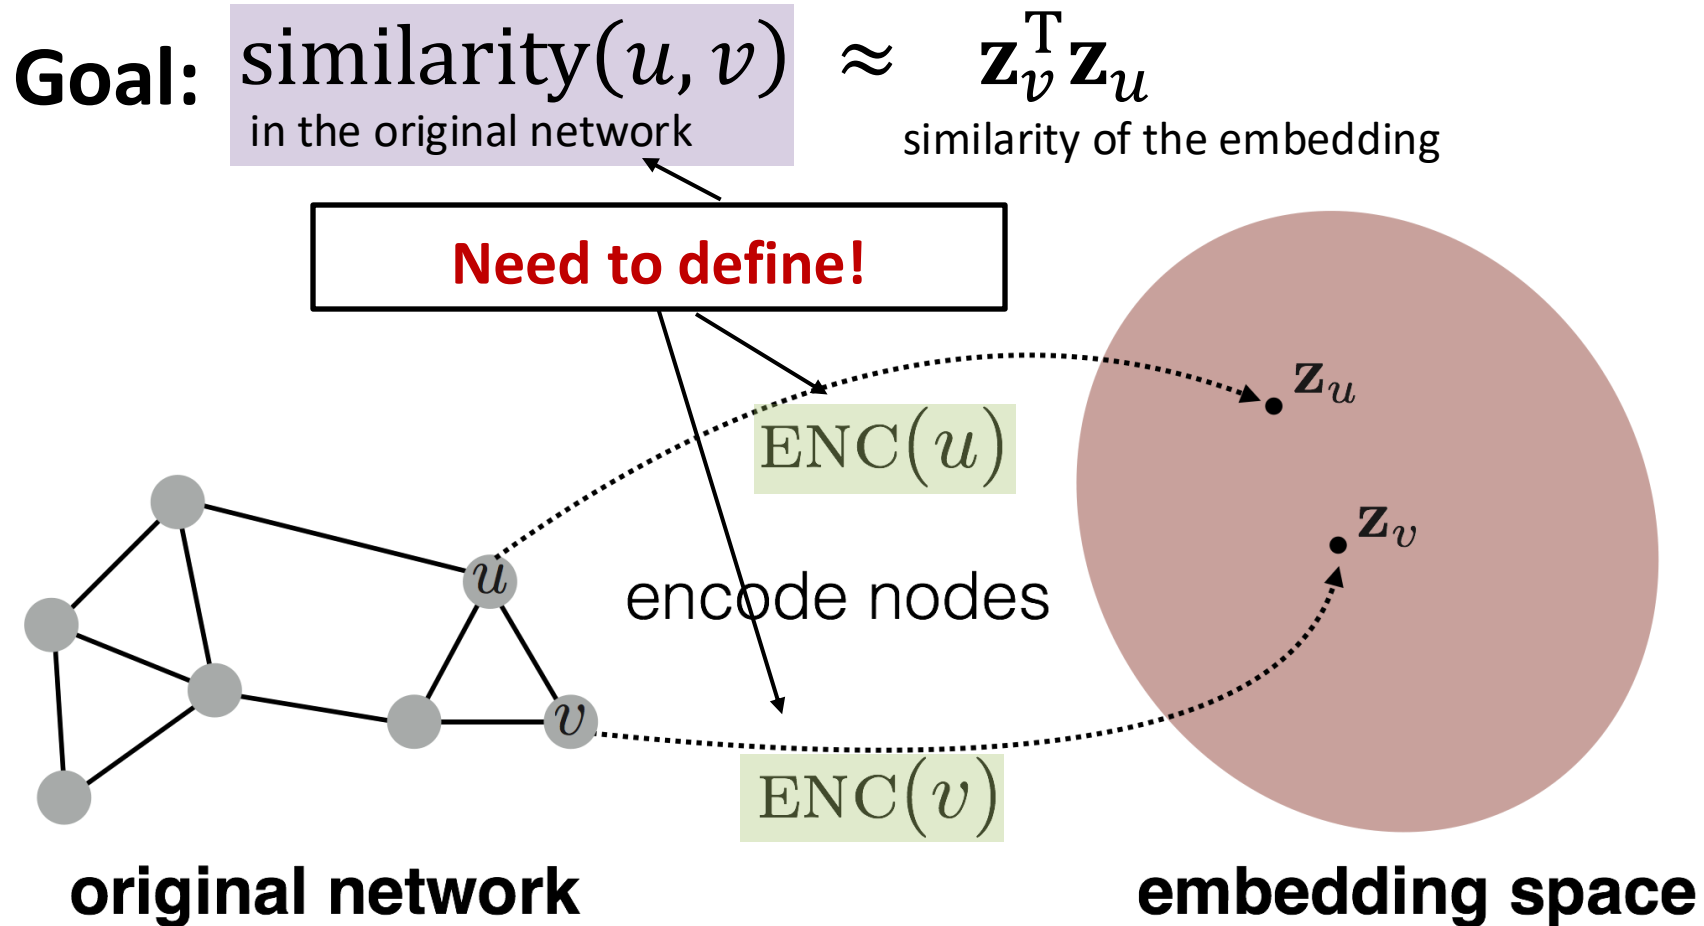

Recap: “Shallow” Encoding

- **Limitations** of shallow embedding methods:
 - **$O(|V|d)$ parameters are needed:**
 - No sharing of parameters between nodes
 - Every node has its own unique embedding
 - **Inherently “transductive”:**
 - Cannot generate embeddings for nodes that are not seen during training
 - **Do not incorporate node features:**
 - Nodes in many graphs have features that we can and should leverage

Recap: Similarity Based Objective Function

- Requires an **edge-level prediction head**

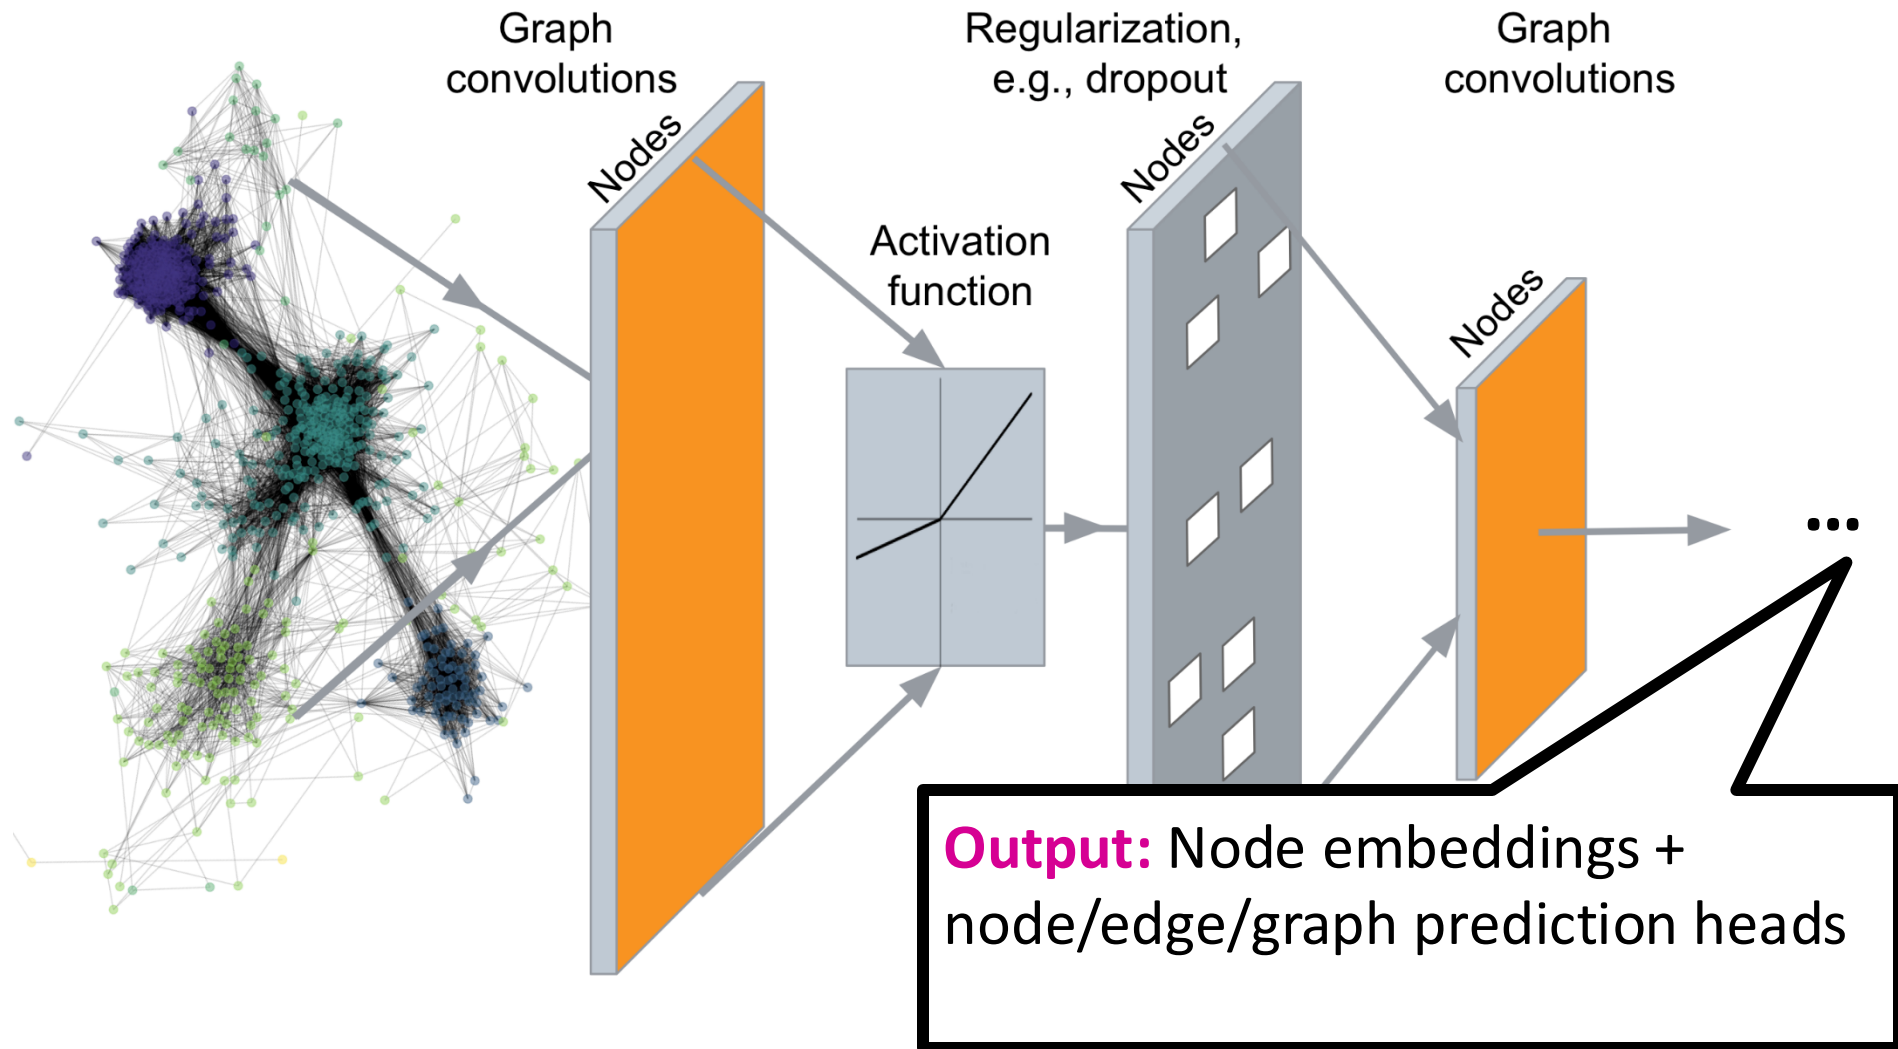

Today: Deep Graph Encoders

- **Today:** We will now discuss deep learning methods based on **graph neural networks (GNNs)**:

$$\text{ENC}(v) = \begin{array}{l} \text{multiple layers of} \\ \text{non-linear transformations} \\ \text{based on graph structure} \end{array}$$

- **Note:** All these deep graph encoders still output node embeddings, and can be **combined with different node/edge/graph prediction heads**

Deep Graph Encoders

Graph Neural Networks: Perspective

Deep Learning for Graphs

Content

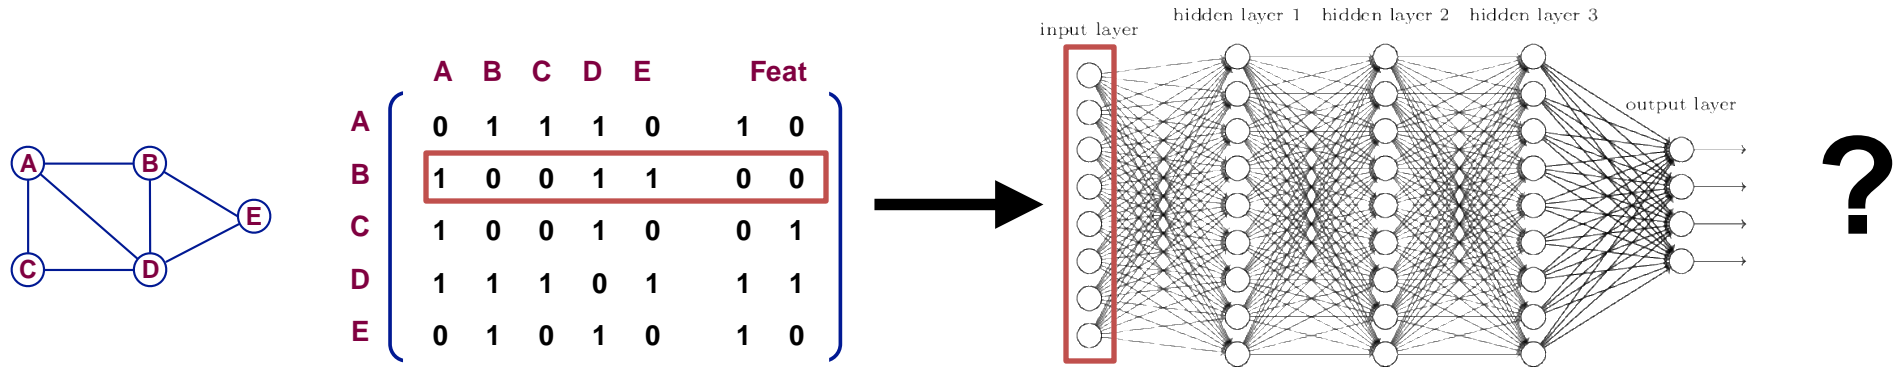

- **Local network neighborhoods:**
 - Describe aggregation strategies
 - Define computation graphs
- **Stacking multiple layers:**
 - Describe the model, parameters, training
 - How to fit the model?
 - Simple example for unsupervised and supervised training

Setup

- Assume we have a graph G :
 - V is the **vertex set**
 - A is the **adjacency matrix** (assume binary)
 - $X \in \mathbb{R}^{|V| \times d}$ is a matrix of **node features**
 - v : a node in V ; $N(v)$: the set of neighbors of v .
 - **Node features:**
 - Social networks: User profile, User image
 - Biological networks: Gene expression profiles, gene functional information
 - When there is no node feature in the graph dataset:
 - Indicator vectors (one-hot encoding of a node)
 - Vector of constant 1: $[1, 1, \dots, 1]$

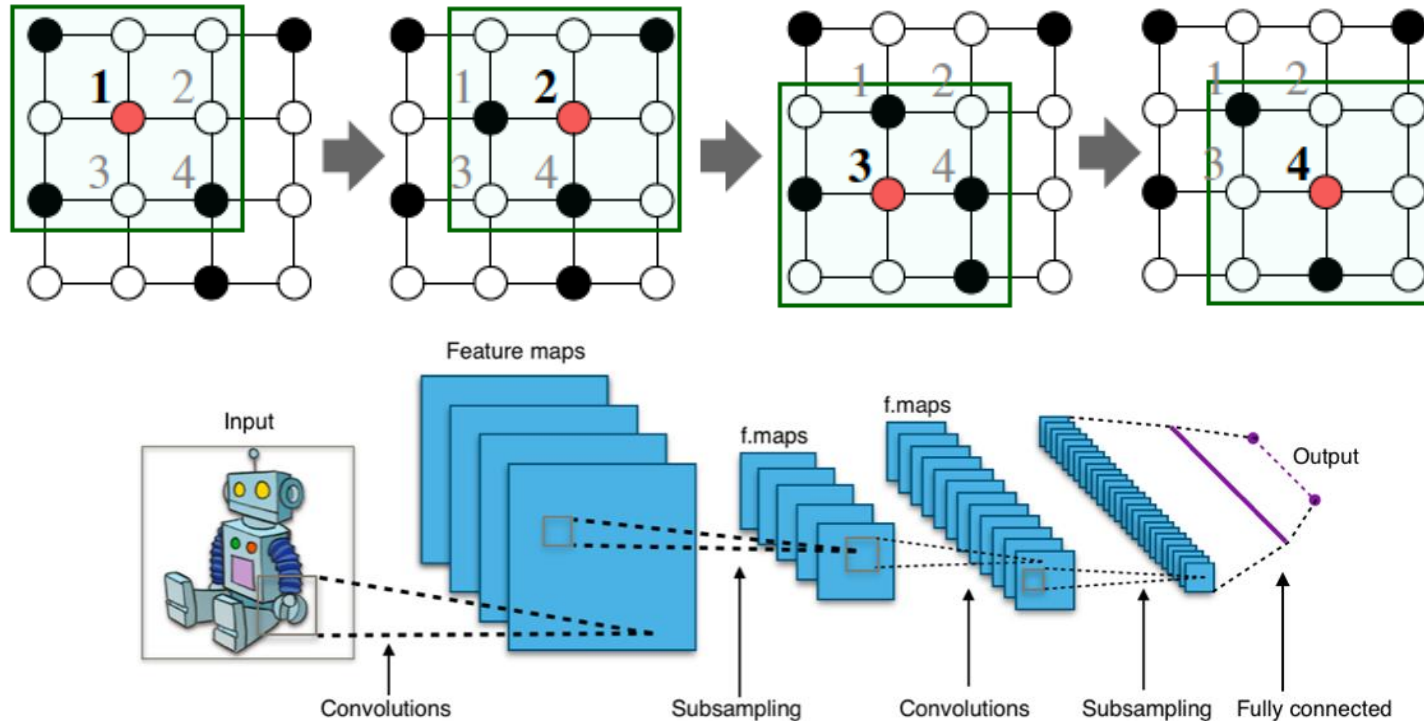

A Naïve Approach

- Join adjacency matrix and features
- Feed them into a deep neural net:

- Issues with this idea:
 - $O(|V|)$ parameters
 - Not applicable to graphs of different sizes
 - Sensitive to node ordering

Idea: Convolutional Networks

Goal is to generalize convolutions beyond simple lattices
Leverage node features/attributes (e.g., text, images)

Real-World Graphs

- But our graphs look like this:

or this:

- There is no fixed notion of locality or sliding window on the graph
- Graph is permutation invariant

Permutation Invariance

- **Graph does not have a canonical order of the nodes!**
- We can have many different order plans.

Permutation Invariance

- Graph does not have a canonical order of the nodes!

Order plan 1

Node features X_1

A	
B	
C	
D	
E	
F	

Adjacency matrix A_1

	A	B	C	D	E	F
A						
B						
C						
D

Permutation Invariance

What does it mean by “graph representation is same for two order plans”?

- Consider we learn a function f that maps a graph $G = (A, X)$ to a vector \mathbb{R}^d then

$$f(A_1, X_1) = f(A_2, X_2)$$

A is the adjacency matrix
 X is the node feature matrix

Order plan 1: A_1, X_1

For two order plans,
output of f should be
the same!

Order plan 2: A_2, X_2

Permutation Invariance

What does it mean by “graph representation is same for two order plans”?

- Consider we learn a function f that maps a graph $G = (A, X)$ to a vector \mathbb{R}^d .
- Then, if $f(A_i, X_i) = f(A_j, X_j)$ for any order plan i and j , we formally say f is a **permutation invariant function**.
- **Definition:** For any **graph** function $f: \mathbb{R}^{|V| \times m} \times \mathbb{R}^{|V| \times |V|} \rightarrow \mathbb{R}^d$, f is **permutation-invariant** if $f(A, X) = f(PAP^T, PX)$ for any permutation P .

A is the adjacency matrix
 X is the node feature matrix

For a graph with $|V|$ nodes,
there are $|V|!$ different
order plans.

Permutation P : a shuffle of
the node order
Example: (A,B,C) \rightarrow (B,C,A)

Permutation Equivariance

- **For node representation:** We learn a function f that maps nodes of G to a matrix $\mathbb{R}^{m \times d}$.

Order plan 1: A_1, X_1

$$f(A_1, X_1) =$$

A	yellow	yellow
B	red	red
C	green	green
D	blue	blue
E	purple	purple
F	pink	pink

Order plan 2: A_2, X_2

$$f(A_2, X_2) =$$

A	pink	pink
B	purple	purple
C	blue	blue
D	green	green
E	yellow	yellow
F	red	red

Permutation Equivariance

- **For node representation:** We learn a function f that maps nodes of G to a matrix $\mathbb{R}^{m \times d}$.

Order plan 1: A_1, X_1

Order plan 2: A_2, X_2

Permutation Equivariance

- **For node representation:** We learn a function f that maps nodes of G to a matrix $\mathbb{R}^{m \times d}$.

Order plan 1: A_1, X_1

Order plan 2: A_2, X_2

Permutation Equivariance

For node representation

- Consider we learn a function f that maps a graph $G = (A, X)$ to a matrix $\mathbb{R}^{m \times d}$
- If the output vector of a node at the same position in the graph remains unchanged for any order plan, we say f is **permutation equivariant**.
- **Definition:** For any **node** function $f: \mathbb{R}^{|V| \times m} \times \mathbb{R}^{|V| \times |V|} \rightarrow \mathbb{R}^{|V| \times m}$, f is **permutation-equivariant** if $Pf(A, X) = f(PAP^T, PX)$ for any permutation P .

Summary: Invariance and Equivariance

- **Permutation-invariant**

$$f(A, X) = f(PAP^T, PX)$$

Permute the input, the output stays the same.
(map a graph to a vector)

- **Permutation-equivariant**

$$Pf(A, X) = f(PAP^T, PX)$$

Permute the input, output also permutes accordingly.
(map a graph to a matrix)

- **Examples:**

- $f(A, X) = \mathbf{1}^T X$: Permutation-**invariant**

- Reason: $f(PAP^T, PX) = \mathbf{1}^T PX = \mathbf{1}^T X = f(A, X)$

- $f(A, X) = X$: Permutation-**equivariant**

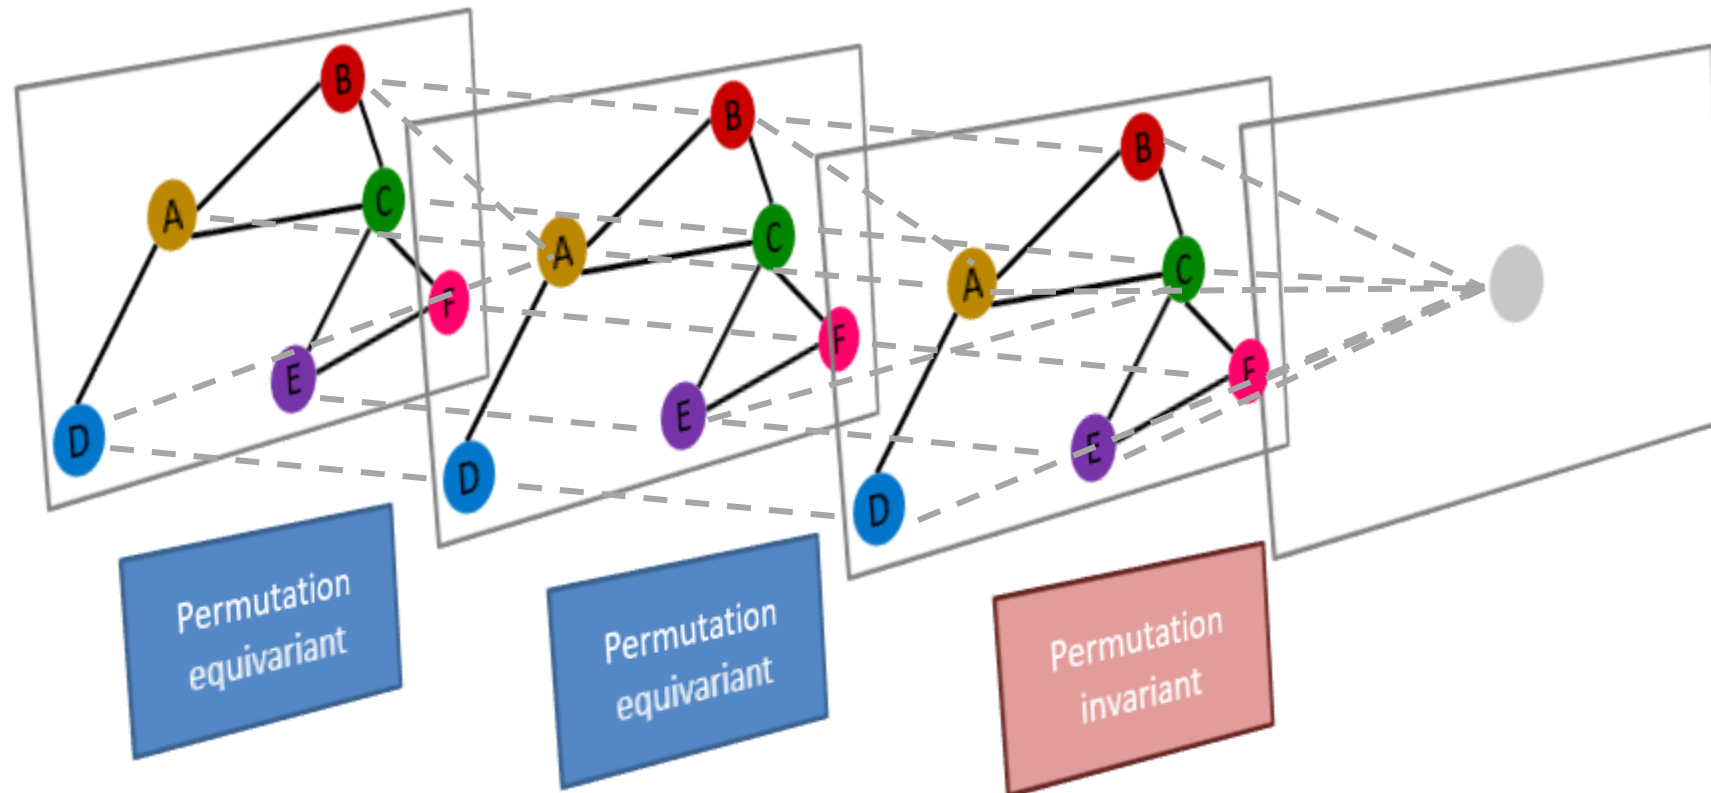

- Reason: $f(PAP^T, PX) = PX = Pf(A, X)$

- $f(A, X) = AX$: Permutation-**equivariant**

- Reason: $f(PAP^T, PX) = PAP^T PX = PAX = Pf(A, X)$

Graph Neural Network Overview

- Graph neural networks consist of multiple permutation equivariant / invariant functions.

Graph Neural Network Overview

Are other neural network architectures, e.g., MLPs, permutation invariant / equivariant?

■ **No.**

Switching the order of the input leads to different outputs!

Graph Neural Network Overview

Are other neural network architectures, e.g., MLPs, permutation invariant / equivariant?

■ **No.**

This explains why **the naïve MLP approach fails for graphs!**

Graph Neural Network Overview

Are other
invariant

■ **No.**

Next: Design graph neural networks
that are permutation invariant /
equivariant by passing and
aggregating information from
neighbors!

?

falls for graphs!

Graph Neural Networks: Perspective

Graph Convolutional Networks

Graph Convolutional Networks

- **Idea:** Node's neighborhood defines a computation graph

Determine node
computation graph

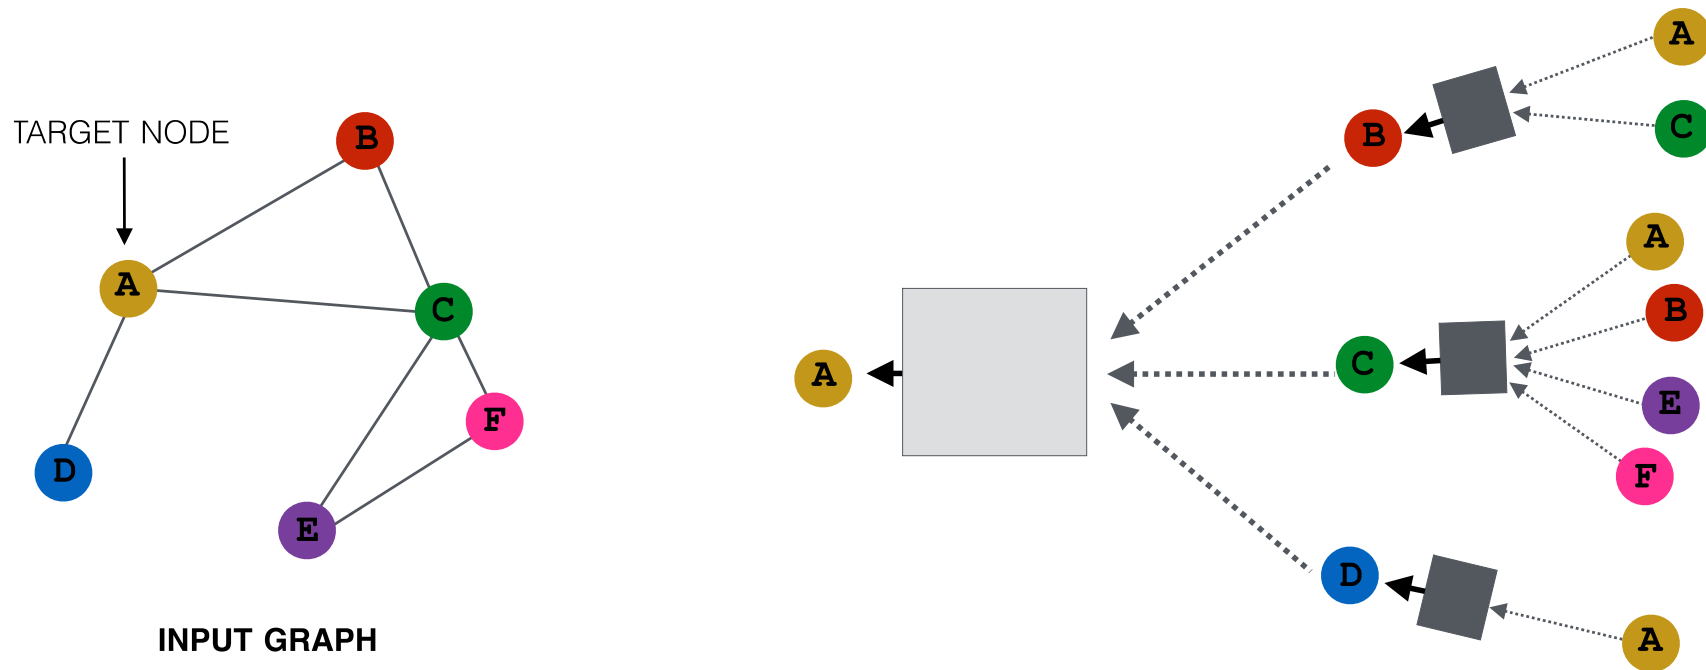

Propagate and
transform information

**Learn how to propagate information across the graph
to compute node features**

Idea: Aggregate Neighbors

- **Key idea:** Generate node embeddings based on **local network neighborhoods**

Idea: Aggregate Neighbors

- **Intuition:** Nodes aggregate information from their neighbors using neural networks

Idea: Aggregate Neighbors

- **Intuition:** Network neighborhood defines a computation graph

Every node defines a computation graph based on its neighborhood!

INPUT GRAPH

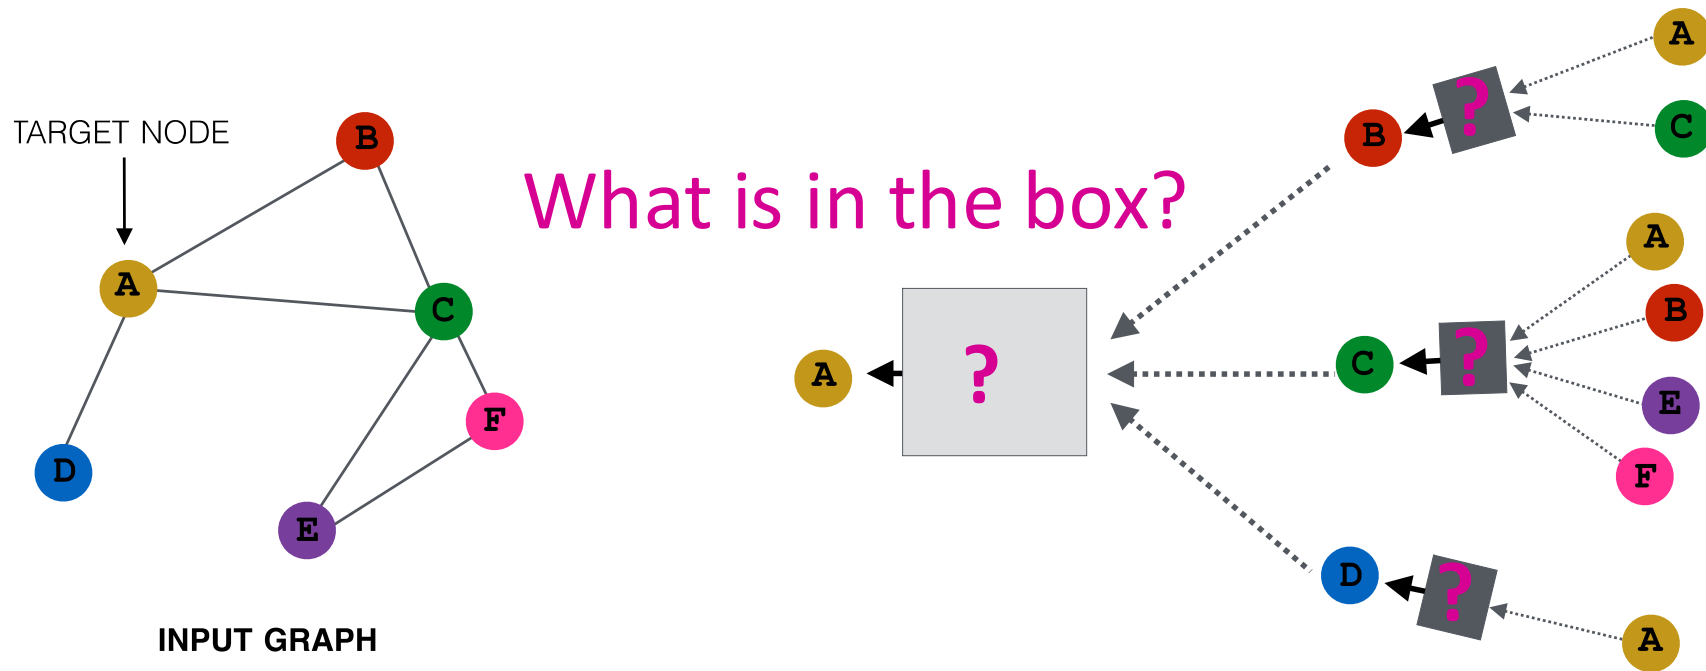

Deep Model: Many Layers

- Model can be of arbitrary depth:
 - Nodes have embeddings at each layer
 - Layer-0 embedding of node v is its input feature, x_v
 - Layer- k embedding gets information from nodes that are k hops away

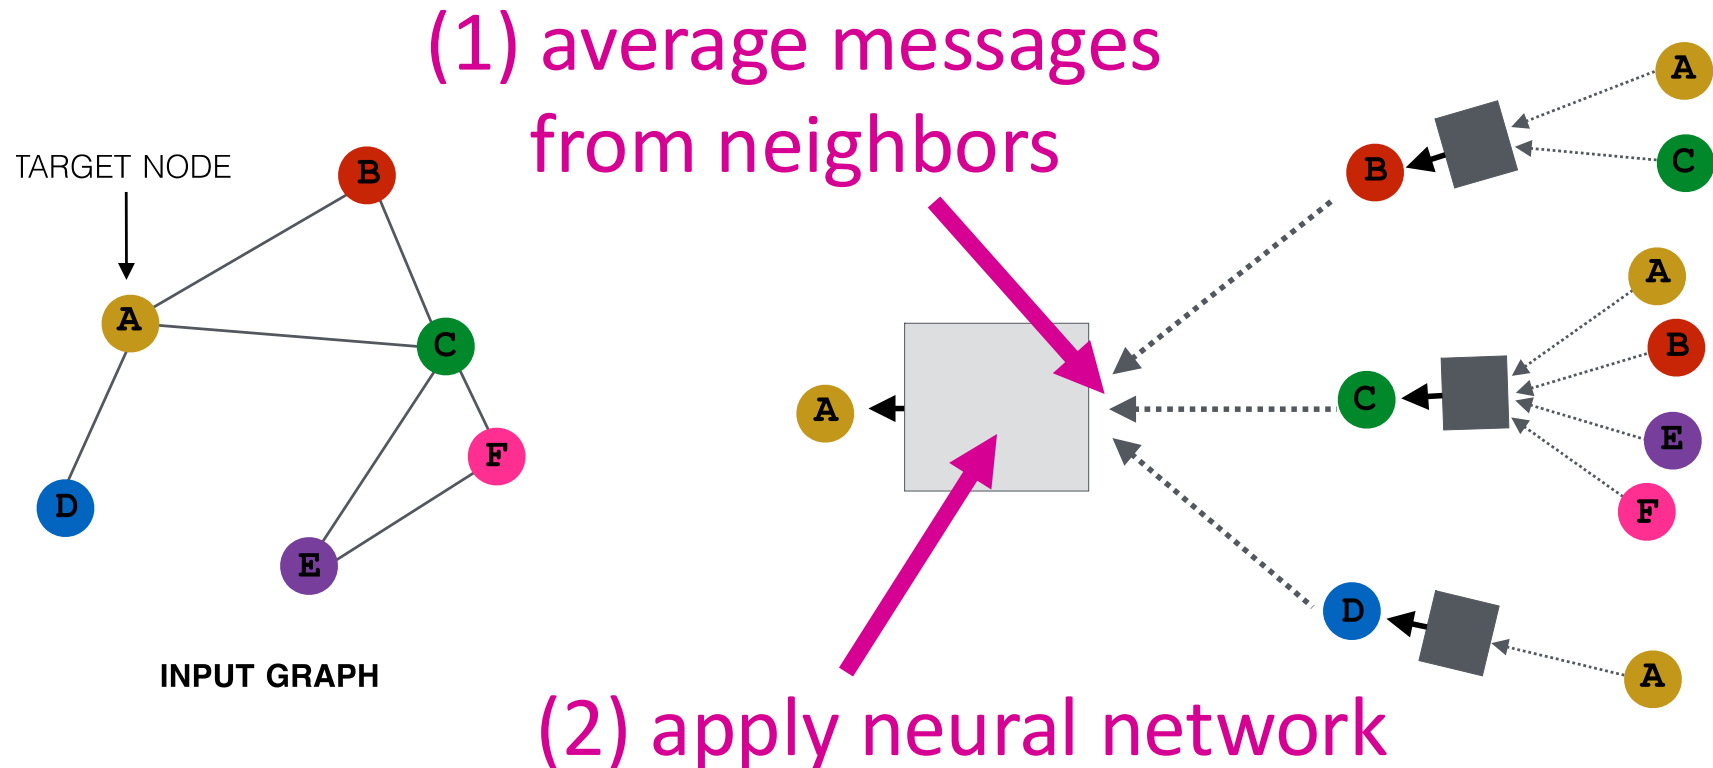

Neighborhood Aggregation

- **Neighborhood aggregation:** Key distinctions are in how different approaches aggregate information across the layers

Neighborhood Aggregation

- **Basic approach:** Average information from neighbors and apply a neural network

The Math: Deep Encoder

- **Basic approach:** Average neighbor messages and apply a neural network

GCN: Invariance and Equivariance

What are the **invariance** and **equivariance** properties for a GCN?

- **Given a node**, the GCN that computes its embedding is **permutation invariant**

Average of neighbor's previous layer embeddings - Permutation invariant

GCN: Invariance and Equivariance

- Considering all nodes in a graph, GCN computation is **permutation equivariant**

Order
plan 1

Order
plan 2

Permute the input, the output also permutes accordingly - **permutation equivariant**

GCN: Invariance and Equivariance

- Considering all nodes in a graph, GCN computation is **permutation equivariant**

Detailed reasoning:

- The rows of **input node features** and **output embeddings** are **aligned**
- We know computing the embedding of a **given node** with GCN is **invariant**.
- So, after permutation, the **location** of a **given node** in the **input node feature** matrix is changed, and the **output embedding** of a **given node** stays the same (the colors of node feature and embedding are **matched**)

This is permutation equivariant

Permute the input, the output also permutes accordingly - **permutation equivariant**

Training the Model

How do we train the GCN to generate embeddings?

Need to define a loss function on the embeddings.

Model Parameters

Trainable weight matrices
(i.e., what we learn)

$$\begin{aligned} h_v^{(0)} &= x_v \\ h_v^{(k+1)} &= \sigma \left(W_k \sum_{u \in N(v)} \frac{h_u^{(k)}}{|N(v)|} + B_k h_v^{(k)} \right), \forall k \in \{0..K-1\} \\ z_v &= h_v^{(K)} \end{aligned}$$

Final node embedding

We can feed these **embeddings into any loss function** and run SGD to **train the weight parameters**

- h_v^k : the hidden representation of node v at layer k
- W_k : weight matrix for neighborhood aggregation
- B_k : weight matrix for transforming hidden vector of self

Matrix Formulation (1)

- Many aggregations can be performed efficiently by (sparse) matrix operations

- Let $H^{(k)} = [h_1^{(k)} \dots h_{|V|}^{(k)}]^T$

- Then: $\sum_{u \in N_v} h_u^{(k)} = A_{v,:} H^{(k)}$

- Let D be diagonal matrix where $D_{v,v} = \text{Deg}(v) = |N(v)|$

- The inverse of D : D^{-1} is also diagonal:
 $D_{v,v}^{-1} = 1/|N(v)|$

- Therefore,

$$\sum_{u \in N(v)} \frac{h_u^{(k-1)}}{|N(v)|} \longrightarrow H^{(k+1)} = D^{-1} A H^{(k)}$$

Matrix of hidden embeddings $H^{(k-1)}$

Matrix Formulation (2)

- Re-writing update function in matrix form:

$$H^{(k+1)} = \sigma(\tilde{A}H^{(k)}W_k^T + H^{(k)}B_k^T)$$

where $\tilde{A} = D^{-1}A$

- Red: neighborhood aggregation
 - Blue: self transformation
- In practice, this implies that efficient sparse matrix multiplication can be used (\tilde{A} is sparse)
 - Note:** not all GNNs can be expressed in matrix form, when aggregation function is complex

How to Train A GNN

- Node embedding \mathbf{z}_v is a function of input graph
- **Supervised setting**: we want to minimize the loss \mathcal{L} (see also Slide 15):

$$\min_{\Theta} \mathcal{L}(\mathbf{y}, f(\mathbf{z}_v))$$

- \mathbf{y} : node label
 - \mathcal{L} could be L2 if \mathbf{y} is real number, or cross entropy if \mathbf{y} is categorical
- **Unsupervised setting**:
 - No node label available
 - **Use the graph structure as the supervision!**

Unsupervised Training

- “Similar” nodes have similar embeddings

$$\mathcal{L} = \sum_{z_u, z_v} \text{CE}(y_{u,v}, \text{DEC}(z_u, z_v))$$

- Where $y_{u,v} = 1$ when node u and v are **similar**
- **CE** is the cross entropy (Slide 16)
- **DEC** is the decoder such as inner product (Lecture 4)
- **Node similarity** can be anything from Lecture 3, e.g., a loss based on:
 - **Random walks** (node2vec, DeepWalk, struc2vec)
 - **Matrix factorization**
 - **Node proximity in the graph**

Supervised Training

- **Directly train** the model for a supervised task (e.g., node classification)

Supervised Training

Directly train the model for a supervised task (e.g., **node classification**)

- Use cross entropy loss (Slide 16)

$$\mathcal{L} = - \sum_{v \in V} y_v \log(\sigma(z_v^T \theta)) + (1 - y_v) \log(1 - \sigma(z_v^T \theta))$$

Encoder output:
node embedding

Node class label

Classification weights

Safe or toxic drug?

Model Design: Overview

(1) Define a neighborhood aggregation function

(2) Define a loss function on the embeddings

Model Design: Overview

INPUT GRAPH

(3) Train on a set of nodes, i.e.,
a batch of compute graphs

Model Design: Overview

INPUT GRAPH

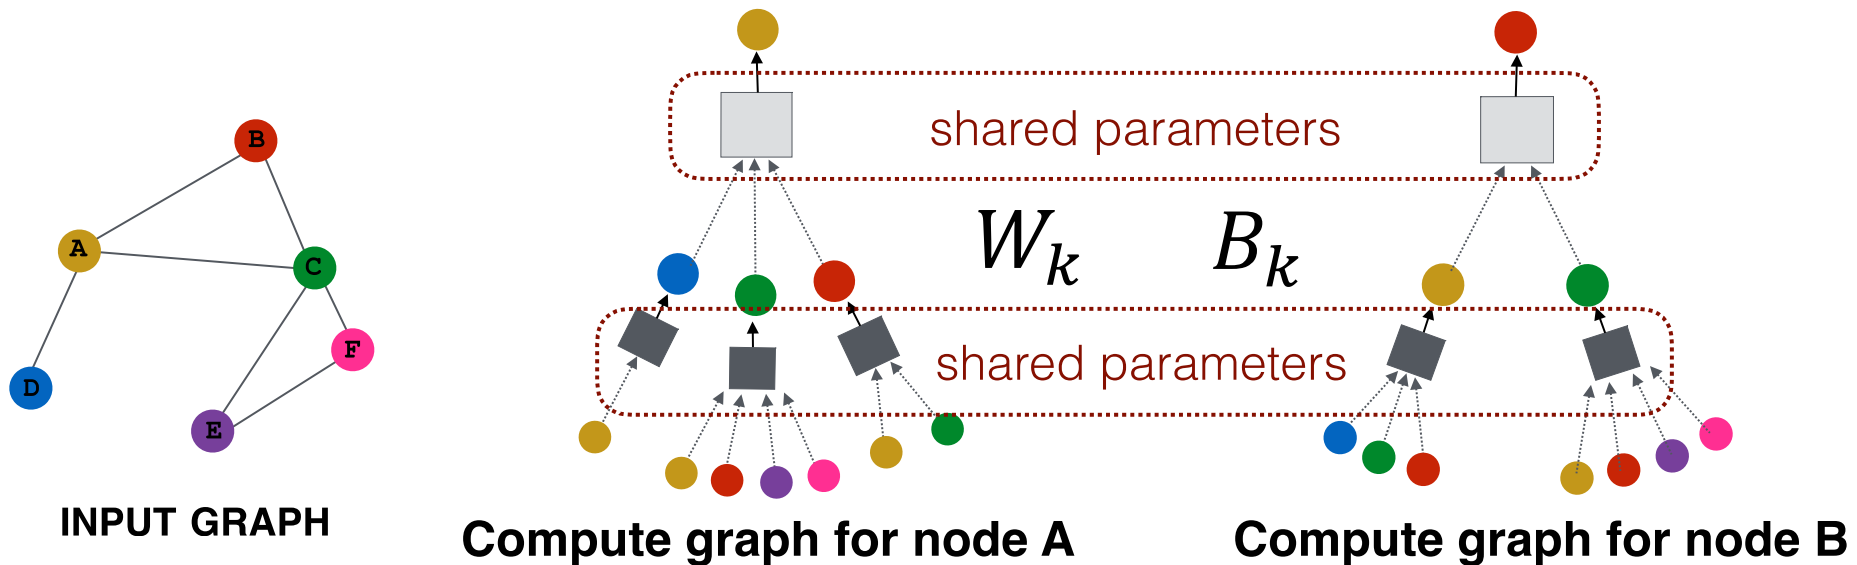

(4) Generate embeddings
for nodes as needed

Even for nodes we never
trained on!

Inductive Capability

- The same aggregation parameters are shared for all nodes:
 - The number of model parameters is sublinear in $|V|$ and we can **generalize to unseen nodes!**

Inductive Capability: New Graphs

Inductive node embedding → Generalize to entirely unseen graphs

E.g., train on protein interaction graph from model organism A and generate embeddings on newly collected data about organism B

Inductive Capability: New Nodes

- Many application settings constantly encounter previously unseen nodes:
 - E.g., Reddit, YouTube, Google Scholar
- Need to generate new embeddings “on the fly”

Summary

- **In this lecture, we introduced**
 - Basics of neural networks
 - Loss, Optimization, Gradient, SGD, non-linearity, MLP
 - Idea for Deep Learning for Graphs
 - Multiple layers of embedding transformation
 - At every layer, use the embedding at previous layer as the input
 - Aggregation of neighbors and self-embeddings
 - Graph Convolutional Network
 - Mean aggregation; can be expressed in matrix form
 - GNN is a general architecture
 - CNN can be viewed as a special GNN

Graph Neural Networks: Perspective

Basics of deep learning

Machine Learning as Optimization

- **Supervised learning:** we are given input x , and the goal is to predict label y .
- **Input x can be:**
 - Vectors of real numbers
 - Sequences (natural language)
 - Matrices (images)
 - Graphs (potentially with node and edge features)
- **We formulate the task as an optimization problem.**

Machine Learning as Optimization

- Formulate the task as an optimization problem:

$$\min_{\Theta} \mathcal{L}(\mathbf{y}, f(\mathbf{x}))$$

Objective function

- Θ : a set of **parameters** we optimize
 - Could contain one or more scalars, vectors, matrices ...
 - E.g. $\Theta = \{Z\}$ in the shallow encoder (the embedding lookup)

- \mathcal{L} : **loss function**. Example: L2 loss

$$\mathcal{L}(\mathbf{y}, f(\mathbf{x})) = \|\mathbf{y} - f(\mathbf{x})\|_2$$

- Other common loss functions:
 - L1 loss, huber loss, max margin (hinge loss), cross entropy ...
 - See <https://pytorch.org/docs/stable/nn.html#loss-functions>

Machine Learning as Optimization

- How to optimize the **objective function**?
- **Gradient vector**: Direction and rate of fastest increase

$$\nabla_{\Theta} \mathcal{L} = \left(\frac{\partial \mathcal{L}}{\partial \Theta_1}, \frac{\partial \mathcal{L}}{\partial \Theta_2}, \dots \right)$$

- $\Theta_1, \Theta_2 \dots$: components of Θ
- Recall **directional derivative** of a multi-variable function (e.g. \mathcal{L}) along a given vector represents the instantaneous rate of change of the function along the vector.
- **Gradient is the directional derivative in the direction of largest increase.**

Partial derivative

<https://en.wikipedia.org/wiki/Gradient>

Gradient Descent

- **Iterative algorithm:** repeatedly update weights in the (opposite) direction of gradients until convergence

$$\Theta \leftarrow \Theta - \eta \nabla_{\Theta} \mathcal{L}$$

- **Training:** Optimize Θ iteratively
 - **Iteration:** 1 step of gradient descent
- **Learning rate (LR) η :**
 - Hyperparameter that controls the size of gradient step
 - Can vary over the course of training (LR scheduling)
- **Ideal termination condition:** gradient = 0
 - In practice, we stop training if it no longer improves performance on **validation set** (part of dataset we hold out from training).

Stochastic Gradient Descent (SGD)

- **Problem with gradient descent:**

- Exact gradient requires computing $\nabla_{\Theta} \mathcal{L}(\mathbf{y}, f(\mathbf{x}))$, where \mathbf{x} is the **entire** dataset!
 - This means summing gradient contributions over all the points in the dataset
 - Modern datasets often contain billions of data points
 - Extremely expensive for every gradient descent step

- **Solution: Stochastic gradient descent (SGD)**

- At every step, pick a different **minibatch** \mathcal{B} containing a subset of the dataset, use it as input \mathbf{x}

Minibatch SGD

- **Concepts:**
 - **Batch size:** the number of data points in a minibatch
 - E.g. number of nodes for node classification task
 - **Iteration:** 1 step of SGD on a minibatch
 - **Epoch:** one full pass over the dataset (# iterations is equal to ratio of dataset size and batch size)
- **SGD is unbiased estimator of full gradient:**
 - But there is no guarantee on the rate of convergence
 - In practice often requires tuning of learning rate
- Common optimizer that improves over SGD:
 - Adam, Adagrad, Adadelta, RMSprop ...

Neural Network Function

- **Objective:** $\min_{\Theta} \mathcal{L}(\mathbf{y}, f(\mathbf{x}))$
- In deep learning, function f can be very complex

- **Example:**

- To start simple, consider linear function

$$f(\mathbf{x}) = \mathbf{W} \cdot \mathbf{x}, \quad \Theta = \{\mathbf{W}\}$$

- Then, if f returns a scalar, then \mathbf{W} is a learnable **vector**

$$\nabla_{\mathbf{W}} f = \left(\frac{\partial f}{\partial w_1}, \frac{\partial f}{\partial w_2}, \frac{\partial f}{\partial w_3} \dots \right)$$

- But, if f returns a vector, then \mathbf{W} is the **weight matrix**

$$\nabla_{\mathbf{W}} f = \begin{bmatrix} \frac{\partial f_1}{\partial w_{11}} & \frac{\partial f_2}{\partial w_{12}} \\ \frac{\partial f_1}{\partial w_{21}} & \frac{\partial f_2}{\partial w_{22}} \end{bmatrix}$$

Jacobian
matrix of f

Intuition: Back Propagation

- **Goal:** $\min_{\Theta} \mathcal{L}(\mathbf{y}, f(\mathbf{x}))$
 - To minimize \mathcal{L} , we need to evaluate the gradient: $\nabla_{\mathbf{W}} \mathcal{L} = \left(\frac{\partial \mathcal{L}}{\partial w_1}, \frac{\partial \mathcal{L}}{\partial w_2}, \frac{\partial \mathcal{L}}{\partial w_3} \dots \right)$
which means we need to derive derivative of \mathcal{L} .
- **Overview of Back-propagation:**
 - \mathcal{L} is composed from some set of predefined building block functions $g(\cdot)$
 - For each such g we also have its derivative g'
 - Then we can automatically compute $\nabla_{\Theta} \mathcal{L}$ by evaluating appropriate funcs. g' on the minibatch \mathcal{B} .

Back-propagation

- How about a more complex function:

$$f(\mathbf{x}) = W_2(W_1\mathbf{x}), \Theta = \{W_1, W_2\}$$

In other words:

$$f(\mathbf{x}) = W_2(W_1\mathbf{x})$$

$$h(x) = W_1\mathbf{x}$$

$$g(z) = W_2z$$

- Recall **chain rule**:

$$\frac{df}{dx} = \frac{dg}{dh} \cdot \frac{dh}{dx} \quad \text{or} \quad f'(x) = g'(h(x))h'(x)$$

- Example:** $\nabla_{\mathbf{x}} f = \frac{\partial f}{\partial (W_1\mathbf{x})} \cdot \frac{\partial (W_1\mathbf{x})}{\partial \mathbf{x}}$

- Back-propagation:** Use of **chain rule** to propagate gradients of intermediate steps, and finally obtain gradient of \mathcal{L} w.r.t. Θ .

Back-propagation Example (1)

- **Example:** Simple 2-layer linear network

- $f(\mathbf{x}) = g(h(\mathbf{x})) = W_2(W_1\mathbf{x})$

- $\mathcal{L} = \sum_{(\mathbf{x}, \mathbf{y}) \in \mathcal{B}} \left\| (\mathbf{y}, -f(\mathbf{x})) \right\|_2$

- The loss \mathcal{L} sums the L2 loss in a minibatch \mathcal{B} .

- **Hidden layer:**

- Intermediate representation of input \mathbf{x}
 - Here we use $h(\mathbf{x}) = W_1\mathbf{x}$ to denote the hidden layer
 - $f(\mathbf{x}) = W_2h(\mathbf{x})$

Back-propagation Example (2)

- Forward propagation:

Compute loss starting from input

- Back-propagation to compute gradient of

$$\Theta = \{W_1, W_2\}$$

Start from loss, compute the gradient

$$\frac{\partial \mathcal{L}}{\partial W_2} = \frac{\partial \mathcal{L}}{\partial f} \cdot \frac{\partial f}{\partial W_2}$$

Compute backwards

$$\frac{\partial \mathcal{L}}{\partial W_1} = \frac{\partial \mathcal{L}}{\partial f} \cdot \frac{\partial f}{\partial W_2} \cdot \frac{\partial W_2}{\partial W_1}$$

Compute backwards

Remember:

$$f(x) = W_2(W_1x)$$

$$h(x) = W_1x$$

$$g(z) = W_2z$$

Non-linearity

- Note that in $f(\mathbf{x}) = W_2(W_1\mathbf{x})$, W_2W_1 is another matrix (vector, if we do binary classification)
 - Hence $f(\mathbf{x})$ is still linear w.r.t. \mathbf{x} no matter how many weight matrices we compose

- **We introduce non-linearity:**

- **Rectified linear unit (ReLU)**

$$\text{ReLU}(x) = \max(x, 0)$$

- **Sigmoid**

$$\sigma(x) = \frac{1}{1 + e^{-x}}$$

Multi-layer Perceptron (MLP)

- Each layer of MLP combines linear transformation and non-linearity:
 - where W_l is weight matrix that transforms hidden representation at layer l to layer $l + 1$
 - b^l is bias at layer l , and is added to the linear transformation of $x^{(l)}$
 - σ is non-linearity function (e.g., sigmoid)
- Suppose x is 2-dimensional, with entries x_1 and x_2

Summary

- **Objective function:**

$$\min_{\Theta} \mathcal{L}(\mathbf{y}, f(\mathbf{x}))$$

- f can be a simple linear layer, an MLP, or other neural networks (e.g., a GNN later)
- Sample a minibatch of input \mathbf{x}
- **Forward propagation:** Compute \mathcal{L} given \mathbf{x}
- **Back-propagation:** Obtain gradient $\nabla_{\mathbf{w}} \mathcal{L}$ using a chain rule.
- Use **stochastic gradient descent (SGD)** to optimize for Θ over many iterations.
