Recap: GNN Theory - Injective Multi-Set Function

Theorem [Xu et al. ICLR 2019]

Any injective multi-set function can be expressed as:

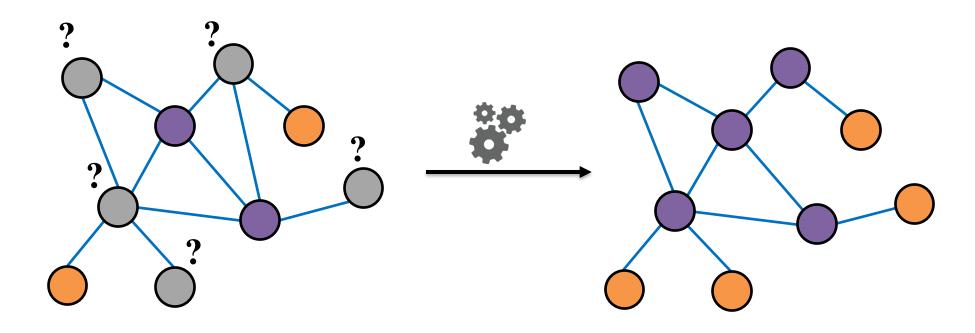

$$S: \text{multi-set}$$

$$\Phi \left(f(\bullet) + f(\bullet) + f(\bullet) \right)$$

Today's Lecture: Outline

- Are there alternative solutions to node embedding based predictions?
- Can we refine the predictions made by GNNs?
- We focus on node-level predictions today
 - Given a network with labels on some nodes, how do we assign labels to all other nodes in the network?
 - **Example:** In a network, some nodes are fraudsters, and some other nodes are fully trusted. **How do you find the other fraudsters and trustworthy nodes?**
- Node embeddings (from random walks, GNN) is a method to solve this problem
 - Are there alternative solutions based on the network topology?

Setting: Node Classification

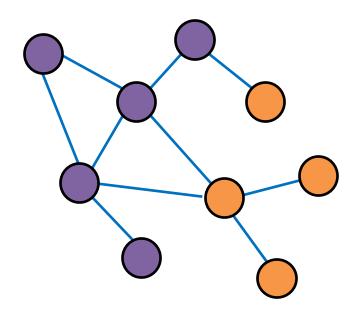

- Given labels of some nodes
- Let's predict labels of unlabeled nodes
- Transductive node classification (test node observable)

Today's Lecture: Outline

- Main question today: Given a network with labels on some nodes, how do we assign labels to all other nodes in the network?
- Today we will discuss an alternative framework: Label propagation
- Intuition: Correlations exist in networks.
 - Connected nodes tend to share the same label
- We will look at three techniques today:
 - Label propagation
 - Correct & Smooth
 - Masked label prediction

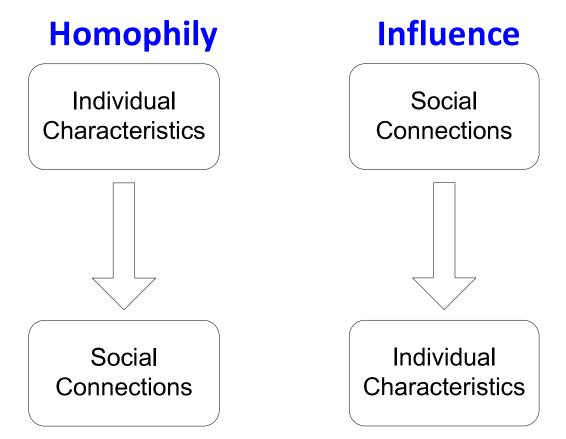

Observation: Correlations in Networks

- Behaviors of nodes are correlated across the links of the network
- Correlation: Nearby nodes have the same color (belonging to the same class)

Correlations Exist in Networks

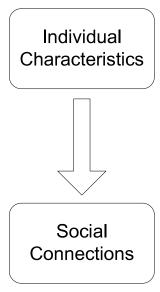

Two explanations for why behaviors of nodes in networks are correlated:

Social Homophily

- Homophily: The tendency of individuals to associate and bond with similar others
 - "Birds of a feather flock together"
 - It has been observed in a vast array of network studies, based on a variety of attributes (e.g., age, gender, organizational role, etc.)
 - Example: Researchers who focus on the same research area are more likely to establish a connection (meeting at conferences, interacting in academic talks, etc.)

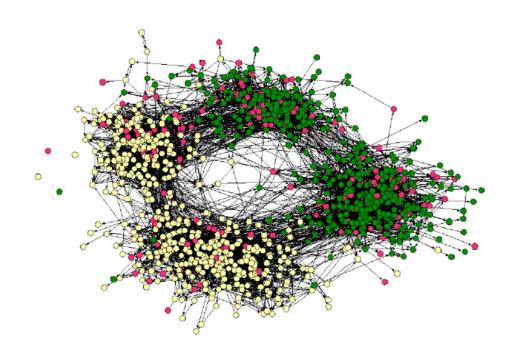

Homophily

Homophily: Example

Example of homophily

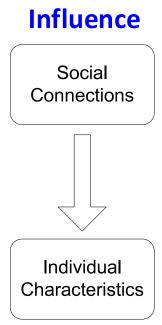

- Online social network
 - Nodes = people
 - Edges = friendship
 - Node color = interests (sports, arts, etc.)
- People with the same interest are more closely connected due to homophily

(Easley and Kleinberg, 2010)

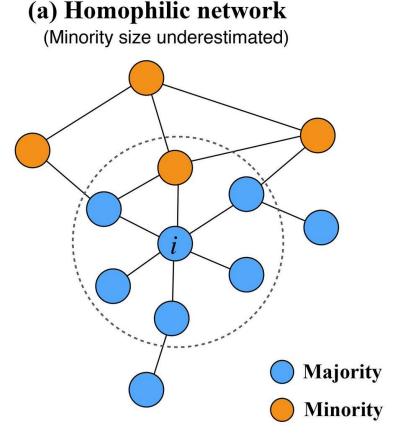

Social Influence: Example

- Influence: Social connections can influence the individual characteristics of a person.
 - Example: I recommend my musical preferences to my friends, until one of them grows to like my same favorite genres!

Homophily vs Heterophily

- Homophily: The tendency of individuals to associate and bond with similar others
- Heterophily: the tendency of individuals to collect in diverse groups; opposite of homophily

(b) Heterophilic network (Minority size overestimated)

Graph Neural Networks: Add-ons

How do we leverage node correlations in networks?

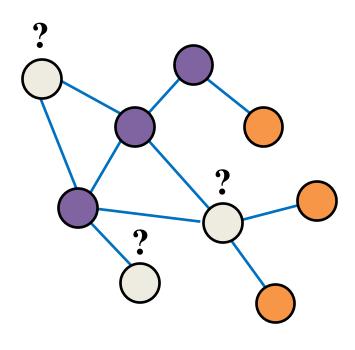

Classification with Network Data

How do we leverage this correlation observed in networks to help predict node labels?

How do we predict the labels for the nodes in grey?

Semi-supervised Learning (1)

- Formal setting:
- Given:
- Graph
- Few labeled nodes

 Find: Class (purple/orange) of remaining nodes

Main assumption: There is homophily in the network

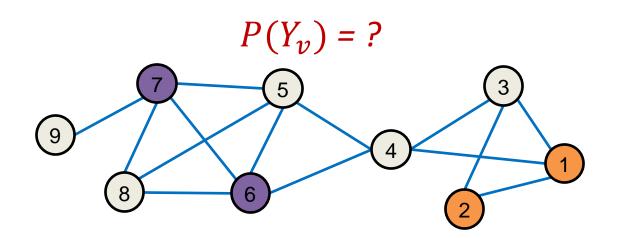

Semi-supervised Learning (2)

Example task:

- Let A be a $n \times n$ adjacency matrix over n nodes
- Let $Y = \{0, 1\}^n$ be a vector of labels:
 - $Y_{\nu} = 1$ belongs to Class 1
 - $Y_{\nu} = 0$ belongs to Class 0
 - There are unlabeled node needs to be classified
- Goal: Predict which unlabeled nodes are likely Class 1, and which are likely Class 0

Problem Setting

- How to predict the labels Y_v for the unlabeled nodes v (in grey color)?
- Each node v has a feature vector f_v
- Labels for some nodes are given (1 for purple, 0 for orange)
- **Task:** Find $P(Y_v)$ given all features and the network

Overview of What is Coming

- We focus on semi-supervised binary node classification
- We will introduce three approaches:
 - Label propagation
 - Correct & Smooth
 - Masked label prediction

Graph Neural Networks: Add-ons Label Propagation

Label Propagation (1)

- Idea: Propagate node labels across the network
 - Class probability Y_v of node v is a weighted average of class probabilities of its neighbors.
- For labeled nodes v, initialize label Y_v with ground-truth label Y_v^* .
- For unlabeled nodes, initialize $Y_v = 0.5$.
- Update all unlabeled nodes (in parallel or a random order) until convergence or until maximum number of iterations is reached.

Label Propagation (2)

• The math: Update each unlabeled node v label

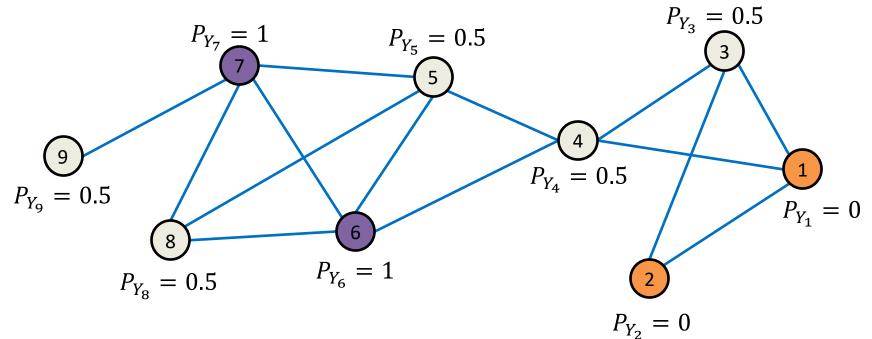

$$P^{(t+1)}(Y_v = c) = \frac{1}{\sum_{(v,u)\in E} A_{v,u}} \sum_{(v,u)\in E} A_{v,u} P^{(t)}(Y_u = c)$$

- If edges have strength/weight information, $A_{v,u}$ can be the edge weight between v and u.
- $P(Y_v = c)$ is the probability of node v having label c.
- Repeated the update until convergence

Example: Initialization

Initialization:

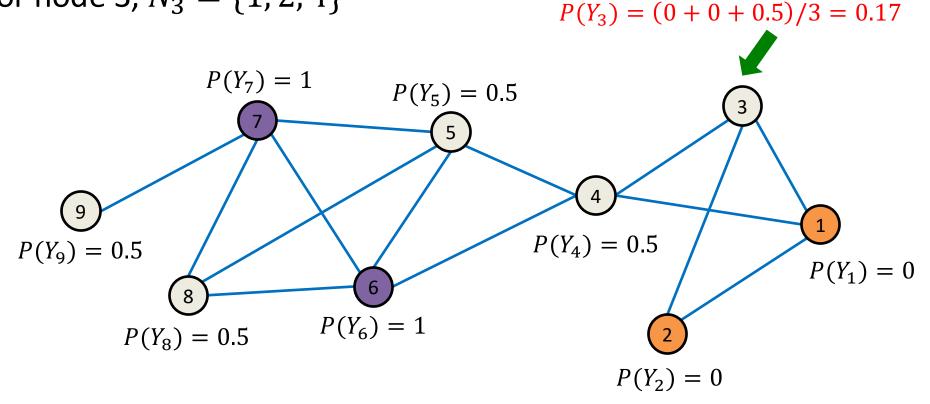

- All labeled nodes with their labels
- All unlabeled nodes 0.5 (belonging to class 1 with probability 0.5)

Notation: $P_{Y_1} = P(Y_1 = 1)$

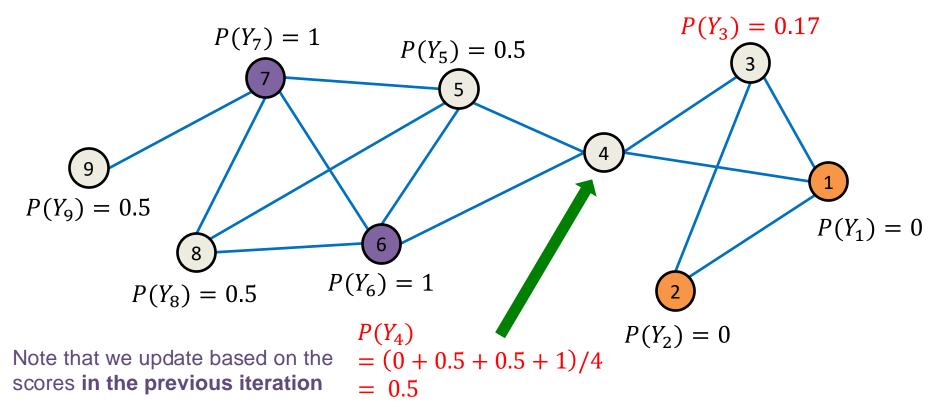

Example: 1st Iteration, Update Node 3

- Update for the 1st Iteration:
 - For node 3, $N_3 = \{1, 2, 4\}$

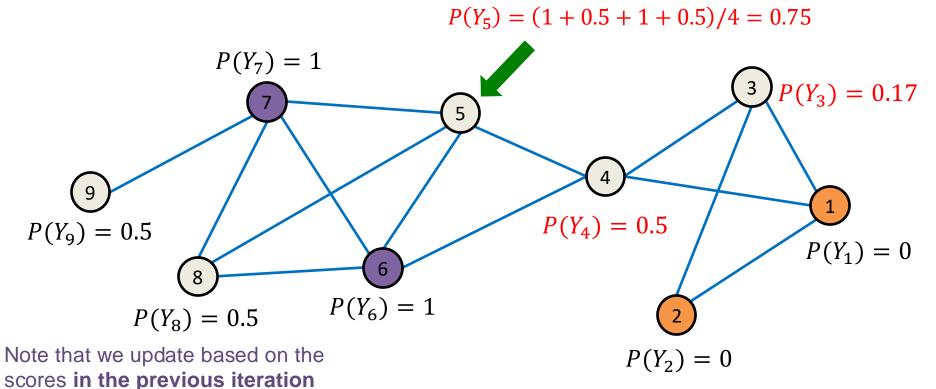

Example: 1st Iteration, Update Node 4

- Update for the 1st Iteration:
 - For node 4, $N_4 = \{1, 3, 5, 6\}$

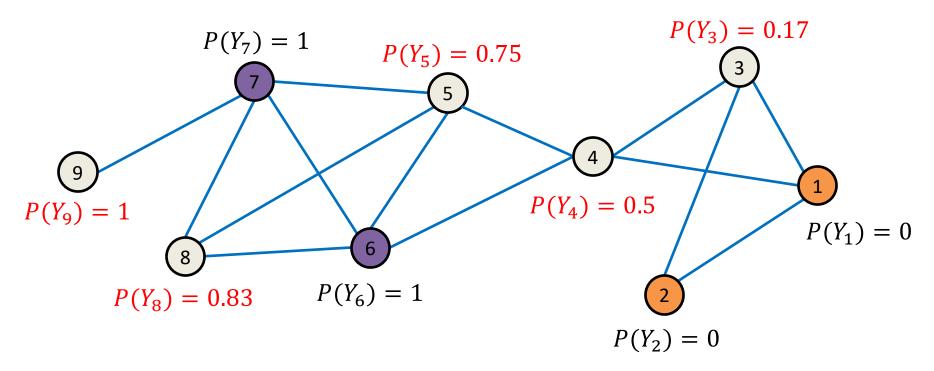

Example: 1st Iteration, Update Node 5

- Update for the 1st Iteration:
 - For node 5, $N_5 = \{4, 6, 7, 8\}$

Example: After 1st Iteration

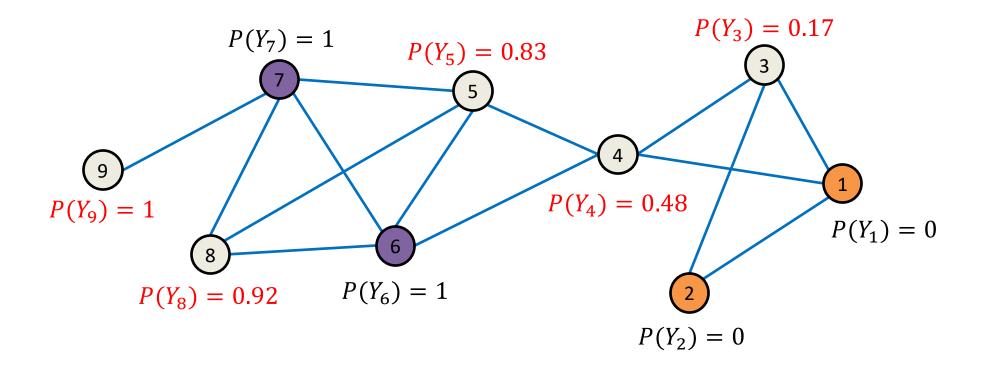

After Iteration 1 (a round of updates for all unlabeled nodes)

Note that we update based on the scores in the previous iteration

Example: After 2nd Iteration

After Iteration 2

Label Propagation: Convergence

- Intuition: Stop iterating when all nodes have approximately reached a static value. Applying label propagation does not change labels anymore.
- Convergence criteria:

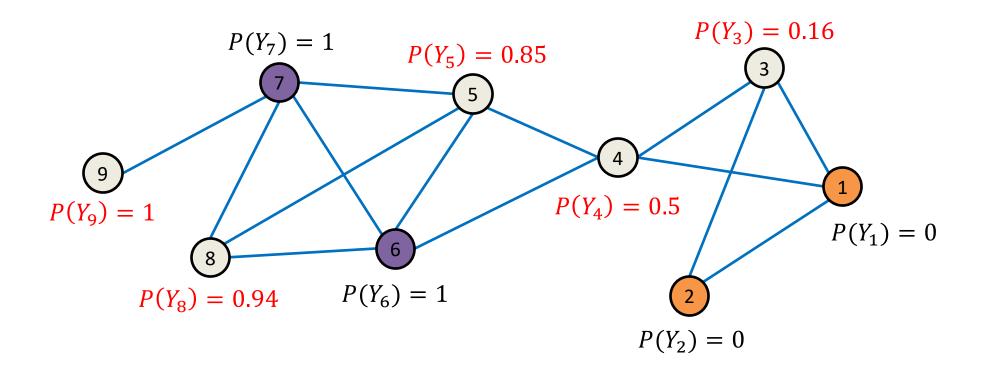

$$\left| P^{(t)}(Y_v) - P^{(t-1)}(Y_v) \right| \le \epsilon$$

for all nodes v. Here ϵ is the convergence threshold.

Whether it will convergence is related to graph's structure (eigen values of the row-normalized adjacency matrix). It will converge for strongly connected, aperiodic graphs.

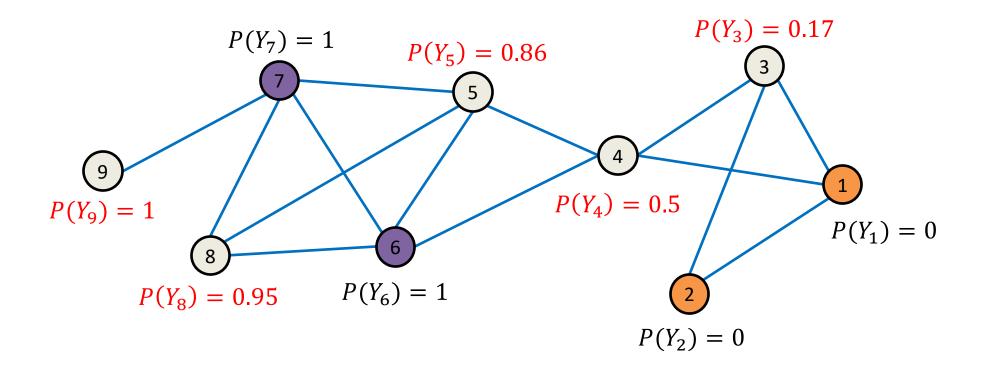

Example: After 3rd Iteration

After Iteration 3

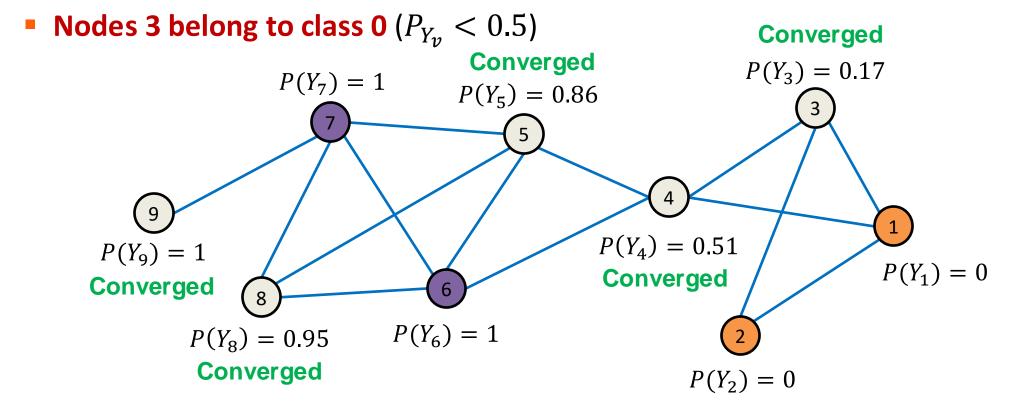

Example: After 4th Iteration

After Iteration 4

Example: Convergence

- All scores stabilize after 4 iterations. We therefore predict:
 - Nodes 4, 5, 8, 9 belong to class 1 ($P_{Y_v} > 0.5$)

Label Propagation Applications

Document classification

- Nodes: documents
- Edges: document similarity (e.g. word overlap)

Twitter polarity classification

- Nodes: users, tweets, words, hashtags, emoji
- Edges [users -> users] Twitter follower graph; Edges [users -> tweets]
 creation;
 - Edges [tweets -> words/hashtags/emoji] part of.

Spam and fraud detection

Summary

Label propagation

 Iteratively update probabilities of node belonging to a label class based on its neighbors

Issue

- Convergence may be very slow and not guaranteed
- Label propagation does not use node attributes
- Can we improve the idea of label propagation to leverage attribute/feature information?

Graph Neural Networks: Add-ons

Node Classification: Correct & Smooth

Correct & Smooth

 Correct & Smooth (C&S), recent state-of-the-art node classification method.

Leaderboard for ogbn-products

The classification accuracy on the test and validation sets. The higher, the better.

Package: >=1.1.1

Rank	Method	Ext. data	Test Accuracy	Validation Accuracy	Contact	References	#Params	Hardware	Date

C&S tops the OGB leaderboard!

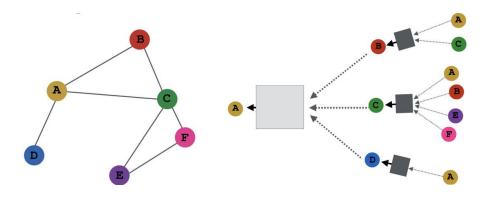

OGB leaderboard snapshot at Jan 30, 2023

Correct & Smooth: Motivations

Label Propagation (LP)

Graph Neural Networks

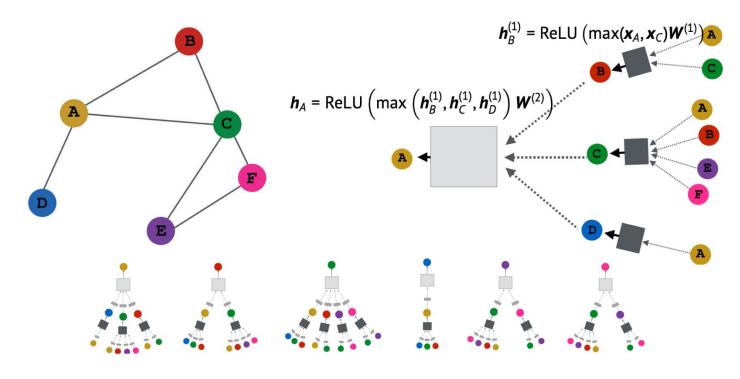

- Modeling assumption: connected nodes have similar labels.
- Works because of homophily a.k.a. associativity
- FAST: few sparse matrix-vector products
- Why not use additional info or features?

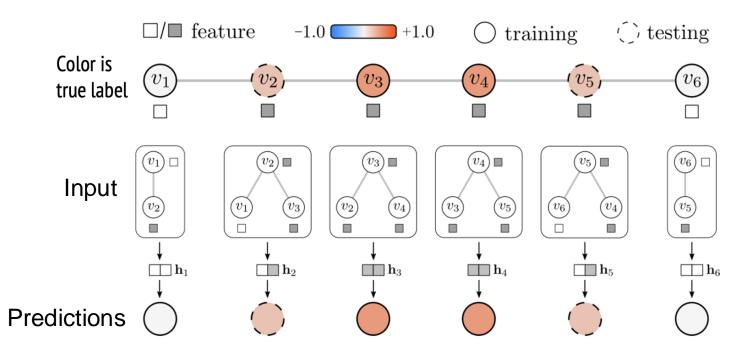

- Modeling assumption: labels only depend on neighbor features.
- Works because these features are sometimes very informative.
- SLOW: many parameters, irregular computation
- Why not assume labels are correlated?

GNNs make uncorrelated predictions

- GNN uses labels to train the weights of a model
 - Given a trained model, predictions for different node are independent/uncorrelated.
- In contrast, LP directly uses the labels in predictions.

GNNs make uncorrelated predictions

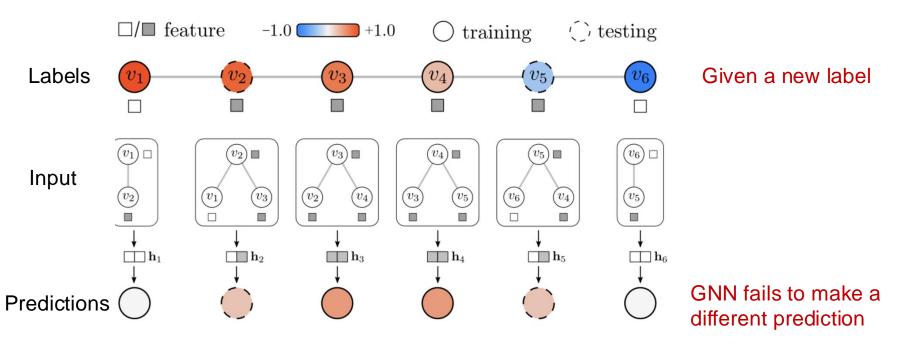

- 1. Form local neighborhoods.
- 2. Combine features to get a representation h_V at node v.
- 3. Predict outcome given representation (learn params with train data).

If node features are overwhelmingly predictive, making uncorrelated predictions for each node is OK.

GNNs make uncorrelated predictions

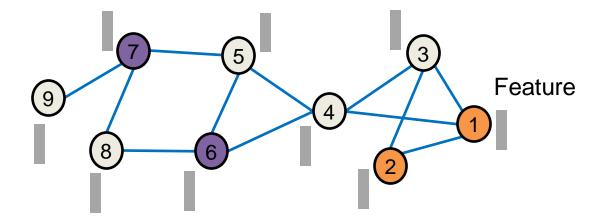

Uncorrelated GNN predictions can be catastrophic in simple cases when features are only mildly predictive.

- Big problem! Features are no longer super predictive.
- LP (ignoring features) would work much better.

Correct & Smooth

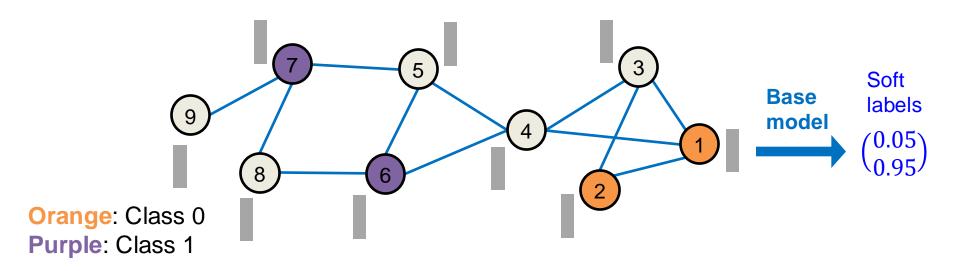

Setting: A partially labeled graph and features over nodes.

- C&S follows the three-step procedure:
 - Train base predictor
 - Use the base predictor to predict soft labels of all nodes.
 - Post-process the predictions using graph structure to obtain the final predictions of all nodes.

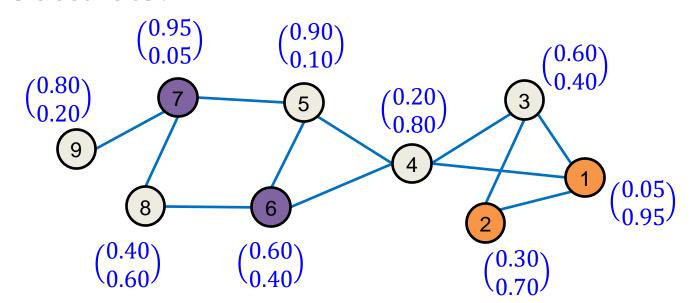

C&S: (1) Train Base Predictor

- (1) Train a base predictor that predict soft labels (class probabilities) over all nodes.
 - Labeled nodes are used for train/validation data.
 - Base predictor can be simple:
 - Linear model/Multi-Layer-Perceptron(MLP) over node features, or a full GNN

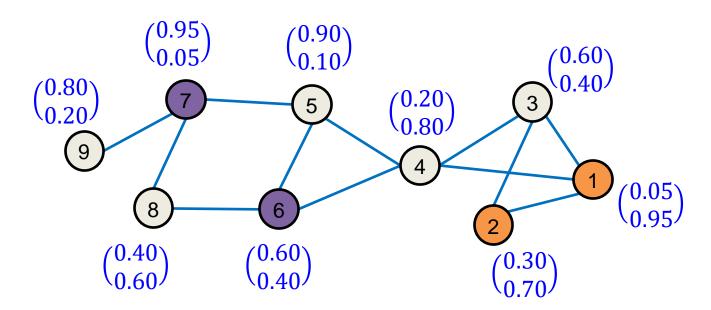

C&S: (2) Predict Over All Nodes

- (2) Given a trained base predictor, we apply it to obtain soft labels for all the nodes.
 - We expect these soft labels to be decently accurate.
 - Can we use graph structure to post-process the predictions to make them more accurate?

C&S: (3) Post-Process Predictions

- (3) C&S uses the 2-step procedure to post-process the soft predictions.
 - Correct step
 - 2. Smooth step

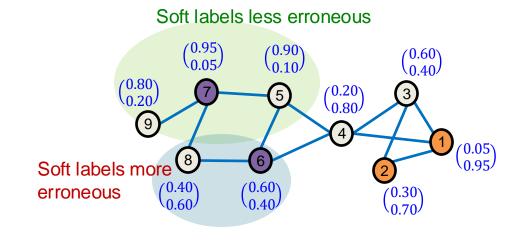

Intuition of Correct & Smooth

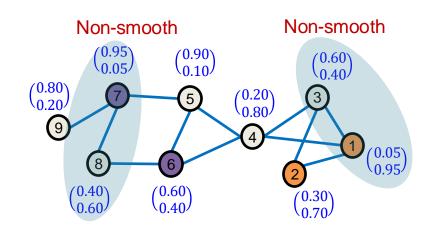

Correct step

- The degree of the errors of the soft labels are biased.
- We need to correct for the error bias.

Smooth step

- The predicted soft labels may not be smooth over the graph.
- We need to smoothen the soft labels.

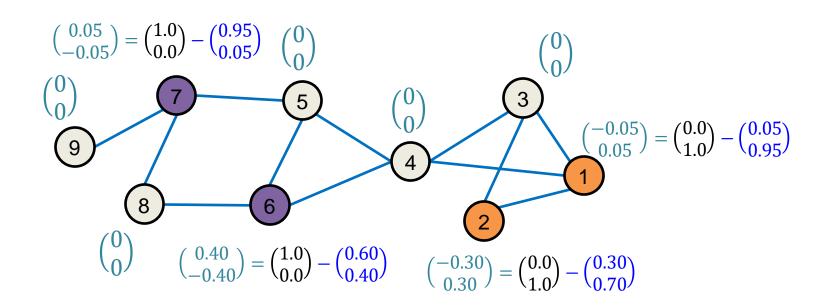

C&S Post-Processing: Correct Step

- The key idea is that we expect errors in the base prediction to be positively correlated along edges in the graph.
 - In other words, an error at node u increases the chance of a similar error at neighbors of u.
 - Thus, we should "spread" such uncertainty over the graph.

C&S Post-Processing: Correct Step (1)

Correct step:

- Compute training errors of nodes.
 - Training error: Ground-truth label minus soft label. Defined as 0 for unlabeled nodes.

C&S Post-Processing: Correct Step (2)

Correct step (contd.):

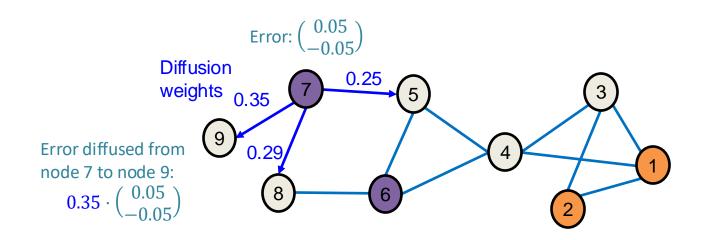

- Diffuse training errors $E^{(0)}$ along the edges.
- Let A be the adjacency matrix, \widetilde{A} be the diffusion matrix (defined in the next slide).
- Hyper-parameter $E^{(t+1)} \leftarrow (1-\alpha) \cdot E^{(t)} + \alpha \cdot \widetilde{A}E^{(t)}$ Diffuse training errors along the edges
 - Similar to PageRank.

Assumption: errors are similar for nearby nodes $\begin{pmatrix}
0.05 \\
-0.05
\end{pmatrix}$ $\begin{pmatrix}
0 \\
0
\end{pmatrix}$ $\begin{pmatrix}
0 \\
0
\end{pmatrix}$ Initial training error $E^{(0)} = \begin{pmatrix}
-0.05 & 0.05 \\
-0.30 & 0.30 \\
0 & 0 \\
0.40 & -0.40
\end{pmatrix}$

matrix

Diffusion Matrix \widetilde{A}

- Normalized diffusion matrix $\widetilde{A} \equiv D^{-1/2}AD^{-1/2}$
 - Add self-loop to the adjacency matrix A, i.e., $A_{ii} = 1$.
 - Let $\mathbf{D} \equiv \text{Diag}(d_1, ..., d_N)$ be the degree matrix.
 - See <u>Zhu et al. ICML 2013</u> for details.

Theoretical Motivation for \widetilde{A}

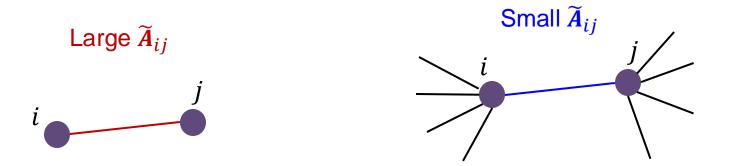

- Normalized diffusion matrix $\widetilde{A} \equiv D^{-1/2}AD^{-1/2}$
- All the eigenvalues λ 's are in the range of [-1,1].
 - Eigenvector for $\lambda = 1$ is $\mathbf{D}^{1/2}\mathbf{1}$ (1 is an all-one vector).
 - Proof: $\widetilde{A}D^{1/2}\mathbf{1} = D^{-1/2}AD^{-1/2}D^{1/2}\mathbf{1} = D^{-1/2}A\mathbf{1} = D^{-1/2}D\mathbf{1} = 1 \cdot D^{1/2}\mathbf{1}$.
 - A1 = D1, since they both leads to node degree vector
 - The power of \widetilde{A} (i.e., \widetilde{A}^K) is well-behaved for any K.
 - The eigenvalues of \widetilde{A}^K are always within [-1,1].
 - The largest eigenvalue is always 1.
 - Output of $\widetilde{A}x$ (e.g., in error diffusion) is normalized

More Intuitions for \widetilde{A}

• If i and j are connected, the weight \widetilde{A}_{ij} is $\frac{1}{\sqrt{d_i}\sqrt{d_j}}$

Intuition:

- Large if i and j are connected only with each other (no other nodes are connected to i and j).
- Small if i and j are connected also connected with many other nodes.

C&S Post-Processing: Correct Step (3)

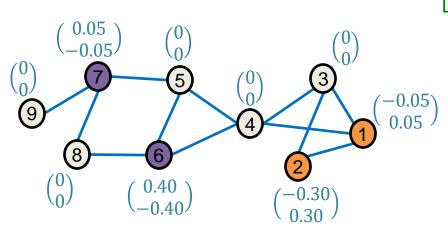

Diffusion of training errors:

$$\mathbf{E}^{(t+1)} \leftarrow (1-\alpha) \cdot \mathbf{E}^{(t)} + \alpha \cdot \widetilde{\mathbf{A}} \mathbf{E}^{(t)}$$

Assumption: Prediction errors are similar for nearby nodes.

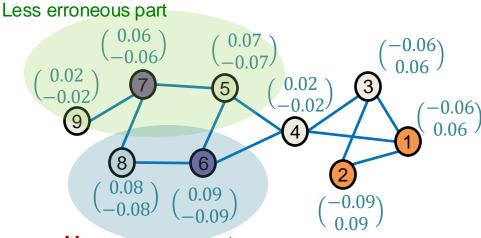

Before diffusion

 $E^{(0)}$

After diffusion

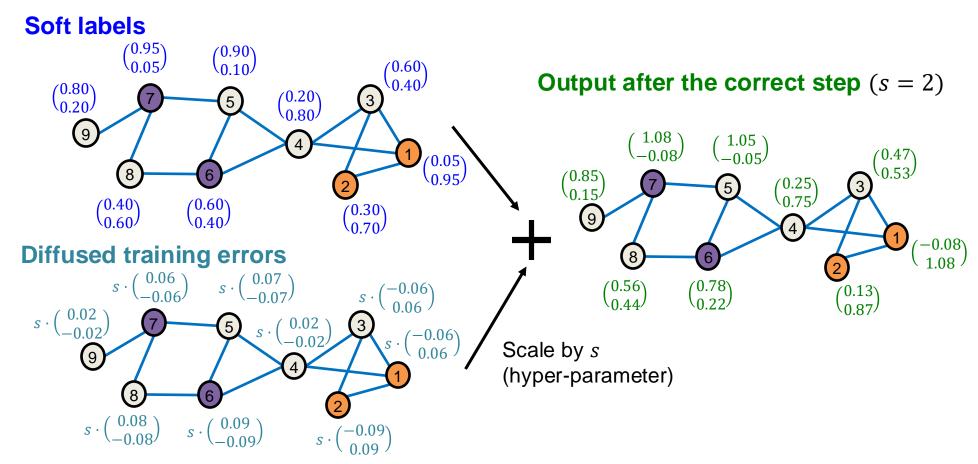

$$E^{(3)}$$
, $\alpha = 0.8$

More erroneous part

C&S Post-Processing: Correct Step (4)

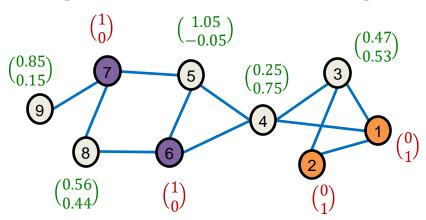

Add the scaled diffused training errors into the predicted soft labels

C&S Post-Processing: Smooth Step

- Smoothen the corrected soft labels along the edges.
 - Assumption: Neighboring nodes tend to share the same labels.
 - Note: For training nodes, we use the ground-truth hard labels instead of the soft labels.

Input to the smooth step:

C&S Post-Processing: Smooth Step (1)

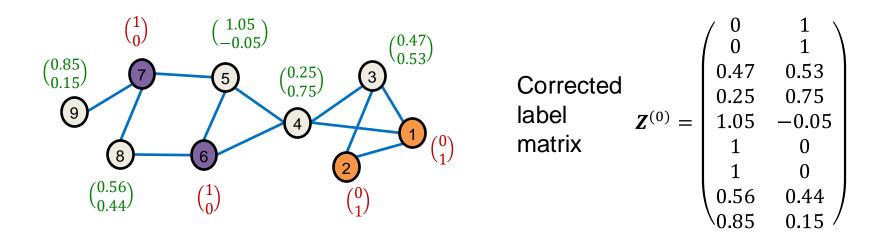

Smooth step:

• Diffuse label $Z^{(0)}$ along the graph structure.

$$Z^{(t+1)} \leftarrow (1 - \alpha) \cdot Z^{(t)} + \alpha \widetilde{A} Z^{(t)}$$

Hyper-parameter

Diffuse labels along the edges

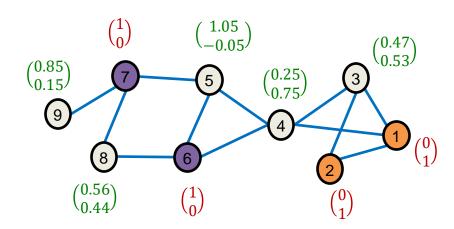

C&S Post-Processing: Correct Step (2)

Smooth step:

$$\mathbf{Z}^{(t+1)} \leftarrow (1 - \alpha) \cdot \mathbf{Z}^{(t)} + \alpha \cdot \widetilde{\mathbf{A}} \mathbf{Z}^{(t)}$$

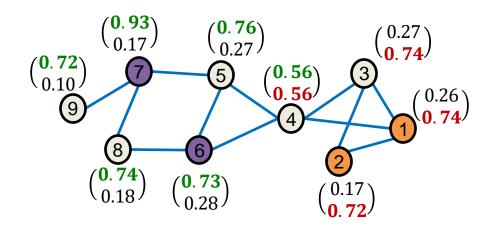

Before smoothing

$$\mathbf{Z}^{(0)}$$

After smoothing

$$Z^{(3)}$$
, $\alpha = 0.8$

The final class prediction of C&S is the class with the maximum $Z^{(3)}$ score.

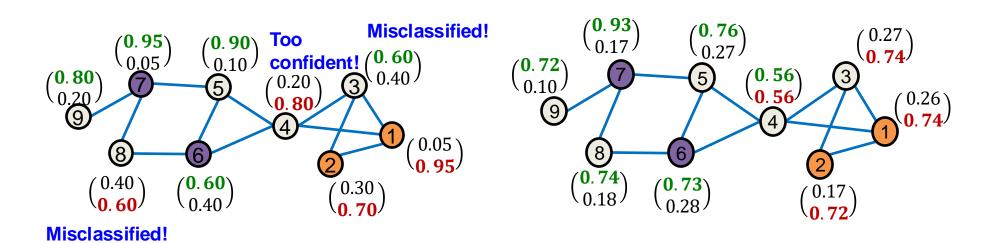

Note: The $Z^{(3)}$ scores do not have direct probabilistic interpretation (e.g., not sum to 1 for each node), but larger scores indicate the classes are more likely.

C&S: Toy Example Summary

 Our toy example shows that C&S successfully improves base model performance using graph structure.

Prediction of the base model

After C&S

C&S on a Real-World Dataset

- C&S significantly improves the performance of the base model (e.g., MLP).
- C&S outperforms Smooth-only (no correct step) baseline.

Method	Classification accuracy (%) on ogbn-products dataset
MLP (base model)	63.41
MLP + smooth only	80.34
MLP + C&S	84.18

Correct & Smooth: Summary

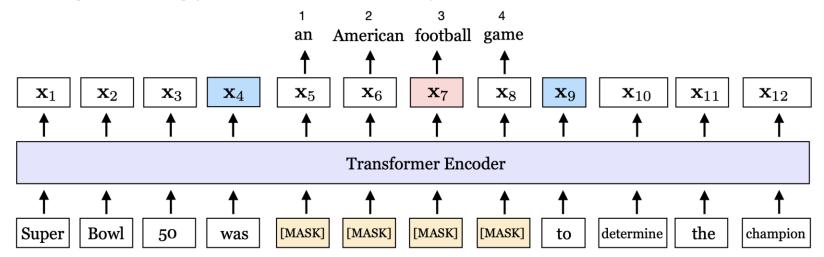

- Correct & Smooth (C&S) uses graph structure to post-process the soft node labels predicted by any base model.
- Correction step: Diffuse and correct for the training errors of the base predictor.
- **Smooth step**: Smoothen the prediction of the base predictor (a variant of **label propagation**).
- C&S can be combined with GNNs
 - C&S achieves strong performance on semi-supervised node classification.

Graph Neural Networks: Add-ons

Masked Label Prediction

Masked Label Prediction

- An alternative approach to explicitly include node label information (works with GNN).
- Inspired from BERT objective in NLP.
 - Pretraining strategy: masked word prediction

Masked Label Prediction

- Idea: Treat labels as additional features
 - Concatenate the node label matrix Y with the node feature matrix X
- ML setting: Use partially observed labels \widehat{Y} to predict the remaining unobserved labels
 - **Training:** First corrupt \widehat{Y} into \widetilde{Y} by randomly masking a portion of node labels to zeros, then use $[X,\widetilde{Y}]$ to predict the masked node labels.
 - Inference: Employ all \hat{Y} to predict the remaining unlabeled nodes (in the validation/test set).
 - Similar to link prediction! Also a self-supervised task

Summary of the Lecture

- We discussed 3 ideas that explicitly use labels when making predictions on graphs
 - Label propagation
 - Directly propagate known labels to all the nodes
 - Correct & Smooth
 - First define a base predictor, then correct and smooth the predictions with label propagation
 - Masked label prediction
 - Construct a self-supervised ML task, let graph ML model to propagate label information
- They serve as alternatives or add-ons to GNNs that we have introduced

Summary of ML with Graphs

- We discussed 3 frameworks to approach machine learning tasks on graphs
- Shallow graph learning
 - Embed nodes into Euclidean space, and use distance metric in embedding space to approximate node similarity
- Graph Neural Networks
 - Iterative neighborhood aggregation
- Label Propagation
 - Inductive bias: homophily
 - Explicitly incorporate label information when making predictions
